

Deep Learning Project Milestones

The following milestones are intended to help you organize your work throughout the semester. They are indicative rather than mandatory, and may be adapted depending on the progress of each project.

Week	Expected Progress
1	Choose the project topic, define the environment, formulate the learning objective, and obtain project approval.
2	Develop a first functional prototype of the environment. The world should already be interactive, even if incomplete.
3	Implement a functional baseline agent (random, heuristic, or rule-based) and define the observations and actions.
4	Train a first deep learning model and obtain initial results, regardless of their quality.
5	Conduct the first experimental study and analyze the obtained behaviors using quantitative metrics.
6	Intermediate project review: present the current progress, discuss encountered difficulties, and define the next objectives.
7	Finalize the environment, improve the agent, perform additional experiments, and prepare the report and demonstration.
8	Final presentation and demonstration of the project. Submit the Git repository, report, and video.

Note. These milestones are intended to provide a suggested rhythm for the project. They are not individual deliverables, but checkpoints to facilitate discussions during the supervised project sessions.
